# Discussion 09

#### Tail Calls, Interpreters

Aditya Balasubramanian aditbala [at] berkeley [dot] edu

#### Announcements <

# Scope \*\*

# Dynamic Scope vs Lexical Scope

- Lexical Scope
  - Parent of function is where function is defined
  - All Python functions and lambda functions in Scheme
- Dynamic Scope
  - Parent of function is where function is called
  - Occurs in mu procedures
  - Will implement this yourself in project!

## Worksheet

# Tail Recursion 5

#### Tail Recursion

- What is Tail Recursion?
  - Recursion while keeping track of our result, instead of accumulating back up at the end
- How do we make our function Tail Recursive?
  - Usually have a helper function to keep track of information from previous frames

#### Tail Calls

- What are Tail Calls?
  - The recursive calls in Tail recursion
- When do they occur?
  - When a function calls another function as the final action of the current frame
  - This also means that the current frame can be discarded (different than normal recursion)
- Why Tail Recursion?
  - More efficient
  - Less Space

# Consider this implementation of factorial that is NOT tail recursive:

- Recursive call is on the last line, but is not the last expression to be evaluated.
- Must accumulate the result of n \* recursive calls at the end

#### Visualization of NON tail-recursive factorial

```
(factorial 6)
(* 6 (factorial 5))
(* 6 (* 5 (factorial 4)))
(* 6 (* 5 (* 4 (factorial 3))))
(* 6 (* 5 (* 4 (* 3 (factorial 2))))
(* 6 (* 5 (* 4 (* 3 (* 2 (factorial 1))))))
(* 6 (* 5 (* 4 (* 3 (* 2 1)))))
(* 6 (* 5 (* 4 (* 3 2))))
(* 6 (* 5 (* 4 6)))
(* 6 (* 5 24))
(*6120)
720
```

### Tail recursive factorial:

```
(define (factorial n)
  (define (fact-tail n result)
     (if (= n 0)
          result
          (fact-tail (- n 1) (* n result))))
  (fact-tail n 1))
```

• fact-tail makes a single recursive call to fact-tail, and that recursive call is the last expression to be evaluated

#### Visualization of tail-recursive factorial

```
(factorial 6)
(fact-tail 6 1)
(fact-tail 5 6)
(fact-tail 4 30)
(fact-tail 3 120)
(fact-tail 2 360)
(fact-tail 1 720)
(fact-tail 0 720)
720
```

#### **Tail Context**

- To determine if a function call is a Tail Call, we have to look for Tail Contexts
- Following expressions are Tail Contexts
  - 1. the second or third operand in an if expression
  - 2. any of the non-predicate sub-expressions in a cond expression (i.e. the second expression of each clause)
  - 3. the last operand in an and or an or expression
  - 4. the last operand in a begin expression's body
  - 5. the last operand in a let expression's body
- What is the tail call in (begin (+ 2 3) (- 2 3) (\* 2 3))
- (\* 2 3) is a tail call because it is the last operand expression to be evaluated

## Worksheet

# nterpreters

# Interpreters

- What is an Interpreter?
  - A program used to understand other programs
- Will be using the Calculator language to look at Scheme Syntax
  - Simplified to have a few operations

# Syntax

- Numbers (Numbers) -> 4, 7
- Arithmetic Procedures (Strings) -> "+"
- Call expressions are similar to Scheme Lists
  - o Going to use Pair Class to represent Calculator expressions
  - 0 (+ 2 3) -> Pair("+", Pair(2, Pair(3, nil)))

### Pair Class

- What is the Pair Class?
  - How we represent expressions
- What is in the class?
  - Has a first and rest attribute
  - Must include nil at the end of expression
- If p is a Pair
  - p.first is the operator
  - o p.rest is the list of operands
  - p.rest.first is the first operand

```
class Pair:
    """Represents the built-in pair data structure in Scheme."""
    def ___init___(self, first, rest):
        self.first = first
        if not scheme_valid_cdrp(rest):
            raise SchemeError("cdr can only be a pair, nil, or a prop
        self.rest = rest
    def map(self, fn):
        """Maps fn to every element in a list, returning a new
        Pair.
        \Rightarrow \Rightarrow Pair(1, Pair(2, Pair(3, nil))).map(lambda x: x * x)
        Pair(1, Pair(4, Pair(9, nil)))
        11 11 11
        assert isinstance(self.rest, Pair) or self.rest is nil, \
            "rest element in pair must be another pair or nil"
        return Pair(fn(self.first), self.rest.map(fn))
```

Q10

# How do we actually interpret?

- Evaluation
  - Interpreter determines type of expression and follows rules to evaluate
  - Know what we are inputting
- Applying
  - Once evaluation is done, can apply procedure to operands
  - Simple for Calculator, apply function to operands

#### **Evaluation Rules**

- Numbers
  - Self Evaluating
- Names
  - Look up in OPERATORS Dictionary
  - "+" maps to a Python function that does the operation
- Call Expression
  - Evaluate operator, evaluate operands, apply operator to operands
- Evaluation is recursive!

# **Apply Rules**

- Apply once Evaluation is done
  - Simple call for Calculator to apply function to operands
  - More complicated for Scheme since users can define their own procedures

# Code for Evaluating and Applying

```
def calc_eval(exp):
    if isinstance(exp, Pair): # Call expressions
        return calc_apply(calc_eval(exp.first), exp.rest.map(calc_
    elif exp in OPERATORS:
                           # Names
        return OPERATORS[exp]
    else:
                                # Numbers
        return exp
def calc_apply(fn, args):
"""Applies a calculator expression to a list of numbers"""
    return fn(args)
```
