# Discussion 02

**Environment Diagrams, Higher-Order Functions** 

Aditya Balasubramanian

aditbala [at] berkeley [dot] edu

### Announcements (

- Complete the midterm 1 exam alteration request form by Thursday 2/2 @ 11:59pm for
- We will provide the **Midterm 1 Study Guide** and scratch paper.

#### **Midterm Advice**

## Environment Diagrams 🜎

#### **Enviroment Diagrams**

- What are they?
  - A way to model how our program runs line by line
  - Keep track of variables, function calls and what they return, etc.
- Why use them?
  - Can help us understand where there is a bug in program (debugging)
  - Useful for other questions (WWPD, coding)
  - Exam points!

#### **Important Concepts**

- Expressions
  - Evaluate to values
  - 0 1 + 1 -> 2
- Statements
  - Bind names to values
  - Names
    - def statements, assignment statements, variable names
  - Values
    - numbers, strings, functions, or other objects
  - o x = 2
  - doesn't return anything

#### **Frames**

- What are they?
  - Frames list the bindings of variables and their corresponding value
- What are they used for?
  - Used to look up the value of a variable
- Global Frame always exists

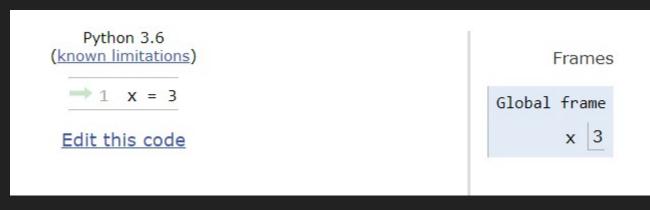

#### **Assignment Statements**

- Assignment statements (denoted by =) creates new binding in frame
- Evaluate right side completely before binding to left side
- Example

```
x = 11 \% 4

y = x

x **= 2
```

#### **Def statements**

- def statements are used to bind function objects to a variable
- Binding name is function name
- Parent of the function is frame where function is defined
- Keep track of name, parameters, parent frame
- Example

```
x = 3
def square(x):
    return x ** 3
square(x)
```

#### **Def statements**

- Only bind, NO execution until function is called
  - o def foo(): -> define function called foo with no parameters
  - o foo() -> execute foo

10

#### **Call Expressions**

- Syntax: function\_name(arg1, arg2, ...)
- sum(square(2), 2 + 2)
- Create new frame for call expression
- Steps for evaluating:
  - i. Evaluate operator (function)
    - See if it exists
      - square(2) -> 4 squares number
      - sum adds two numbers
  - ii. Evaluate operands (args)
    - simplify args
      - 2 + 2 **->** 4
  - iii. Apply operator to the operands
    - $\blacksquare$  sum(4, 4) -> 8

#### **Creating New Frames**

- Give frame with unique index (f1, f2, f3)
- Label frame with name of function object
  - not always the variable name
- Label function's parent (frame in which it is defined in)
- Every function has return value
  - Return value can be None

#### **Variable Lookup**

- Start in current frame
- If variable does not exist, search parent frame
- If variable still does not exist, continue looking in parent frames
- If variable does not exist, program errors

#### Question 1 (5 minutes)

Let's put it all together! Draw an environment diagram for the following code. You may not have to use all of the blanks provided to you.

```
def double(x):
    return x * 2

hmmm = double
wow = double(3)
hmmm(wow)
```

#### **Question 2 (walkthrough)**

Draw the environment diagram that results from executing the code below.

(note: evaluate, then assign)

```
def f(x):
     return x
def g(x, y):
    if x(y):
         return not y
     return y
x = 3
x = g(f, x)

f = g(f, 0)
```

15

### lambda Functions \(\lambda\)

#### lambda Functions λ

- What are they?
  - A quicker and simpler way to define a function
  - Can also be used as the operator for a function
- Why use them?
  - o Useful for scenarios in which you only want to use a function once and never again
- Syntax
  - written in 1 line
  - lambda <args> : <body>

17

#### lambda Function Examples Pt. 1

```
def add_and_square(x, y, z):
    return (x + y + z) ** 2

lambda_add_and_square = lambda x, y, z : (x + y + z) ** 2
```

```
def error():
    return 1 + 2 / 0

lambda_error = lambda : 1 + 2 / 0
```

```
>>> lambda x : x // 3
>>> (lambda x : x // 3)(5)
>>> wow = lambda x: lambda y: lambda z: x * y * z
>>> WOW(3)(7)(5)
\rightarrow >  (lambda x: x(3,4))(lambda a,b: a ** b)
```

```
>>> lambda x : x // 3
Function
>>> (lambda x : x // 3)(5)
>>> wow = lambda x: lambda y: lambda z: x * y * z
>>> WOW(3)(7)(5)
>>> (lambda x: x(3,4))(lambda a,b: a ** b)
```

```
>>> lambda x : x // 3
Function
>>> (lambda x : x // 3)(5)
>>> wow = lambda x: lambda y: lambda z: x * y * z
>>> WOW(3)(7)(5)
>>> (lambda x: x(3,4))(lambda a,b: a ** b)
```

```
>>> lambda x : x // 3
Function
>>> (lambda x : x // 3)(5)
>>> wow = lambda x: lambda y: lambda z: x * y * z
>>> WOW(3)(7)(5)
105
>>> (lambda x: x(3,4))(lambda a,b: a ** b)
```

```
>>> lambda x : x // 3
Function
>>> (lambda x : x // 3)(5)
>>> wow = lambda x: lambda y: lambda z: x * y * z
>>> WOW(3)(7)(5)
105
\rightarrow \rightarrow (lambda x: x(3,4))(lambda a,b: a ** b)
81
```

#### Question 3 (10 minutes)

Draw the environment diagram for the following code and predict what Python will output.

```
a = lambda x: x * 2 + 1
def b(b, x):
    return b(x + a(x))
x = 3
x = b(a, x)
```

### Higher Order Functions 2 2 2

#### **Higher Order Functions (HOF)**

- What are they?
  - Functions that either return functions as output or take in other functions as inputs
- Why use them?
  - When you want to use a function within another function
  - Treat them as an object
- Important Note
  - Let's see we have function foo() that takes in zero parameters
  - foo refers to the function object and is NOT calling the function
  - foo() shows that we are actually calling the function

#### **HOF Function as Input Example**

```
>>> def exec_func(func, a):
       return func(a)
>>> exec_func(lambda x : x * 4, 4)
>>> exec_func(lambda x : pow(x, 2), 2)
```

27

#### **HOF Function as Output Example**

PythonTutor

```
>>> def first(x):
         def square(y):
              def mod(z):
                   return (x ** y) % z
              return mod
         return square
>>> a = first(2)
\Rightarrow \Rightarrow b = a(4)
>>> b(3)
```

28

#### **HOF Function as Output Example**

```
>>> def first(x):
        def square(y):
            def mod(z):
                 return (x ** y) % z
            return h
        return g
>>> a = first(2)
>>> b = a(4)
>>> b(3)
```

#### **Question 4**

Draw the environment diagram for the following code and predict what Python will output.

```
n = 9
def make_adder(n):
    return lambda k: k + n
add_ten = make_adder(n+1)
result = add_ten(n)
```

30

#### **Question 5**

Write a function that takes in a number n and returns a function that can take in a single parameter cond. When we pass in some condition function cond into this returned function, it will print out numbers from 1 to n where calling cond on that number returns True.

```
def make_keeper(n):
```

### Thank you!
